### Algorithms and Abstract Data Types

### Induction Proofs

Let  $P(n)$  be a propositional function, i.e.  $P$  is a function whose domain is (some subset of) the set of integers and whose codomain is the set  $\{\text{True}, \text{False}\}$ . Informally, this means  $P(n)$  is a sentence, statement, or assertion whose truth or falsity depends on the integer  $n$ . *Mathematical Induction* is a method for proving statements of the form  $\forall n \geq n_0 : P(n)$  (“for all  $n$  greater than or equal to  $n_0$ ,  $P(n)$  is true”), where  $n_0$  is a fixed integer. A proof by Mathematical Induction contains two steps:

**I. Base Step:** Prove directly that the proposition  $P(n_0)$  is true.

**IIa. Induction Step:** Prove  $\forall n \geq n_0 : P(n) \rightarrow P(n+1)$ .

To do this, pick an arbitrary  $n \geq n_0$ , and assume for this  $n$  that  $P(n)$  is true. Then show as a consequence that  $P(n+1)$  is true. The statement  $P(n)$  is often called the *induction hypothesis*, since it is what is assumed in the induction step.

When I and II are complete we conclude that  $P(n)$  is true for all  $n \geq n_0$ . Induction is sometimes explained in terms of a domino analogy. Consider an infinite set of dominos that are lined up and ready to fall. Each domino is labeled by a positive integer, starting with  $n_0$ . (Often  $n_0 = 1$ , which we assume here for the sake of definiteness). Let  $P(n)$  be the assertion: “the  $n$ th domino falls”. First prove  $P(1)$ , i.e. “the first domino falls”, then prove  $\forall n \geq 1 : (P(n) \rightarrow P(n+1))$  which says “if any particular domino falls, then the next domino must also fall”. When this is done, we may conclude  $\forall n \geq 1 : P(n)$ , “all dominos fall”. There are a number of variations on the induction step. The first is just a re-parametrization of IIa.

**IIb. Induction Step:** Prove  $\forall n > n_0 : P(n-1) \rightarrow P(n)$

Let  $n > n_0$ , assume  $P(n-1)$  is true, then prove  $P(n)$  is true.

Forms **IIa** and **IIb** are said to be based on the *first principle of mathematical induction*. The validity of this principle is proved in the appendix of this handout. Another important variation is called the *second principle of mathematical induction*, or *strong induction*, and is illustrated below.

**IIc. Induction Step:** Prove  $\forall n \geq n_0 : (\forall k \leq n : P(k)) \rightarrow P(n+1)$

Let  $n \geq n_0$ , assume for all  $k$  in the range  $n_0 \leq k \leq n$  that  $P(k)$  is true. Then prove as a consequence that  $P(n+1)$  is true. In this case the term *induction hypothesis* refers to the stronger assumption:  $\forall k \leq n : P(k)$ , which can also be written  $P(n_0) \wedge P(n_0 + 1) \wedge \dots \wedge P(n)$ .

The strong induction form is often re-parameterized as in **IIId**:

**IIId. Induction Step:** Prove  $\forall n > n_0 : (\forall k < n : P(k)) \rightarrow P(n)$

Let  $n > n_0$ , assume for all  $k$  in the range  $n_0 \leq k < n$ , that  $P(k)$  is true, then prove  $P(n)$  is true. In this case, the *induction hypothesis* is  $\forall k < n : P(k)$ , or  $P(n_0) \wedge P(n_0 + 1) \wedge \dots \wedge P(n-1)$ .

In terms of the Domino analogy, the strong induction form IId says we must show: (I) the first domino falls, and (II) for any  $n$ , if all dominos up to but not including the  $n^{\text{th}}$  domino fall, then the  $n^{\text{th}}$  domino falls. From (I) and (II) we may conclude that all dominos fall. Strong Induction is most often parameterized as in IId, and form IIc is uncommon. We present here a number of examples of IIa, IIb, and IId.

**Example 1** Prove that for all  $n \geq 1$ :

$$\boxed{\sum_{i=1}^n i^2 = \frac{n(n+1)(2n+1)}{6}}$$

**Proof:**

Let  $P(n)$  be the boxed equation above. We begin the induction at  $n_0 = 1$ .

**I. Base step** Clearly  $\sum_{i=1}^1 i^2 = 1 = \frac{1 \cdot (1+1) \cdot (2 \cdot 1 + 1)}{6}$ , showing that  $P(1)$  is true.

**IIa. Induction Step** Let  $n \geq 1$  and assume  $P(n)$  is true. That is, for this particular value of  $n$ , the boxed equation holds. Then

$$\begin{aligned} \sum_{i=1}^{n+1} i^2 &= \sum_{i=1}^n i^2 + (n+1)^2 \\ &= \frac{n(n+1)(2n+1)}{6} + (n+1)^2 && \text{(by the induction hypothesis)} \\ &= \frac{n(n+1)(2n+1) + 6(n+1)^2}{6} \\ &= \frac{(n+1) \cdot [(n+1)+1] \cdot [2(n+1)+1]}{6} && \text{(by some algebra)} \end{aligned}$$

showing that  $P(n+1)$  is true.

We conclude that  $P(n)$  is true for all  $n \geq 1$ . ■

There are several points of correctness and clarity to remember when writing an induction proof. Always explicitly state (1) the induction hypothesis, and (2) the statement to be proved on the induction step. Also (3) make note of the point in the proof where the induction hypothesis is used.

**Example 2** Let  $x \in R$  and  $x \neq 1$ . Show that for all  $n \geq 0$ :

$$\boxed{\sum_{i=0}^n x^i = \frac{x^{n+1} - 1}{x - 1}}$$

**Proof:**

Here we will use form IIb. Again let  $P(n)$  be the boxed equation. We begin the induction at  $n_0 = 0$ .

**I. Base step**  $\sum_{i=0}^0 x^i = x^0 = 1 = \frac{x-1}{x-1}$ , showing that  $P(0)$  is true.

**IIb. Induction Step** Let  $n > 0$  and assume that  $P(n-1)$  is true, i.e. assume for this particular  $n$  that:

$\sum_{i=0}^{n-1} x^i = \frac{x^n - 1}{x - 1}$ . Then to show  $P(n)$ ,  $\sum_{i=0}^n x^i = \frac{x^{n+1} - 1}{x - 1}$ , we have

$$\begin{aligned} \sum_{i=0}^n x^i &= \sum_{i=0}^{n-1} x^i + x^n \\ &= \frac{x^n - 1}{x - 1} + x^n && \text{(by the induction hypothesis)} \\ &= \frac{x^{n+1} - 1}{x - 1} && \text{(by some algebra)} \end{aligned}$$

showing that  $P(n)$  is true.

Steps I and II prove that  $P(n)$  holds for all  $n \geq 0$ . ■

**Exercise 1** Prove the following formulas using both induction step forms **IIa** and **IIb**.

- Show that for all  $n \geq 1$ :  $\sum_{i=1}^n i^3 = \left( \frac{n(n+1)}{2} \right)^2$ .
- Show that for all  $n \geq 1$ :  $\sum_{i=1}^n i^4 = \frac{n(n+1)(2n+1)(3n^2+3n-1)}{30}$ .

Often the proposition to be proved is not an equation, but some other type of assertion, like an inequality, as in the following example.

**Example 3** Define the function  $T(n)$  for  $n \in \mathbb{Z}^+$  by the recurrence

$$T(n) = \begin{cases} 0 & \text{if } n = 1 \\ T(\lfloor n/2 \rfloor) + 1 & \text{if } n \geq 2 \end{cases}$$

Prove that for all  $n \geq 1$ ,  $\boxed{T(n) \leq \lg(n)}$ , and therefore  $T(n) = O(\lg n)$ .

**Proof:**

Let  $P(n)$  be the boxed inequality above.

**I. Base Step**

The inequality  $T(1) \leq \lg(1)$  reduces to  $0 \leq 0$ , which is obviously true, so  $P(1)$  holds.

**II. Induction Step**

Let  $n > 1$  and assume for all  $k$  in the range  $1 \leq k < n$  that  $P(k)$  is true, i.e.  $T(k) \leq \lg(k)$ . In particular when  $k = \lfloor n/2 \rfloor$ , we have  $T(\lfloor n/2 \rfloor) \leq \lg \lfloor n/2 \rfloor$ . We must show  $T(n) \leq \lg(n)$ .

$$\begin{aligned} T(n) &= T(\lfloor n/2 \rfloor) + 1 && \text{(by the definition of } T(n) \text{)} \\ &\leq \lg \lfloor n/2 \rfloor + 1 && \text{(by the induction hypothesis)} \\ &\leq \lg(n/2) + 1 && \text{(since } \lfloor x \rfloor \leq x \text{ for any } x \text{)} \\ &= \lg(n) - \lg(2) + 1 \end{aligned}$$

$$= \lg(n),$$

showing that  $P(n)$  is true, and therefore  $T(n) \leq \lg(n)$  for all  $n \geq 1$ , as claimed. ■

**Exercise 2** Define  $S(n)$  for  $n \in \mathbb{Z}^+$  by the recurrence

$$S(n) = \begin{cases} 0 & \text{if } n = 1 \\ S(\lceil n/2 \rceil) + 1 & \text{if } n \geq 2 \end{cases}$$

Prove that for all  $n \geq 1$ :  $S(n) \geq \lg(n)$ , and hence  $S(n) = \Omega(\lg n)$ .

There are many other variations on the Induction Principles (both weak and strong). Occasionally it is necessary to prove multiple base cases.

**Base Step:** Prove  $P(1), P(2), \dots, P(n_0)$ .

**Induction Step (weak version):** Prove  $\forall n > n_0 : P(n-1) \rightarrow P(n)$ .

**Induction Step (strong version):** Prove  $\forall n > n_0 : (P(1) \wedge P(2) \wedge \dots \wedge P(n-1)) \rightarrow P(n)$ .

**Conclusion:**  $\forall n \geq 1 : P(n)$ .

**Example 4** Define a function  $T(n)$  by the following recurrence.

$$T(n) = \begin{cases} 1 & \text{if } 1 \leq n \leq 2 \\ 4T(\lfloor n/3 \rfloor) + n & \text{if } n \geq 3 \end{cases}$$

Show that  $\boxed{T(n) \leq n^2}$  for all  $n \geq 1$  (and hence  $T(n) = O(n^2)$ .)

**Proof:**

Let  $P(n)$  be the boxed inequality above.

**I. Base Step**

Observe  $T(1) = 1 \leq 1^2$  and  $T(2) = 1 \leq 2^2$ , so both  $P(1)$  and  $P(2)$  are true.

**II. Induction Step (strong version)**

Let  $n > 2$  and assume for all  $k$  in the range  $1 \leq k < n$  that  $P(k)$  is true, i.e.  $T(k) \leq k^2$ . In particular when  $k = \lfloor n/3 \rfloor$ , we have  $T(\lfloor n/3 \rfloor) \leq \lfloor n/3 \rfloor^2$ . We must show  $T(n) \leq n^2$  is true.

$$\begin{aligned} T(n) &= 4T(\lfloor n/3 \rfloor) + n && \text{(by the definition of } T(n) \text{)} \\ &\leq 4\lfloor n/3 \rfloor^2 + n && \text{(by the induction hypothesis)} \\ &\leq 4(n/3)^2 + n && \text{(since } \lfloor x \rfloor \leq x \text{ for any } x) \\ &= \frac{4}{9}n^2 + n \\ &\leq n^2 \end{aligned}$$

The last inequality follows from  $n > 2 \Rightarrow \frac{9}{5} \leq n \Rightarrow n \leq \frac{5}{9}n^2 \Rightarrow \frac{4}{9}n^2 + n \leq n^2$ . Hence  $P(n)$  is true, and therefore  $T(n) \leq n^2$  for all  $n \geq 1$ , as claimed. ■

To see why two base cases were necessary in this last example, consider exactly which prior values are needed to compute each  $T(n)$ .

$n$	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	...
$\lfloor n/3 \rfloor$	·	·	1	1	1	2	2	2	3	3	3	4	4	4	5	5	5	6	...

It's as if there are two independent sets of dominoes in this induction proof. One set tracing back to the base case  $n = 1$ , and the other set tracing back to  $n = 2$ . For instance, the statements  $P(3), P(4)$  and  $P(5)$  all depend on  $P(1)$ , while  $P(6), P(7)$  and  $P(8)$  depend on  $P(2)$ . If the base case  $n = 2$  had been left out, then the truth of statements  $P(6), P(7)$  and  $P(8)$  would not follow. Likewise any statement, such as  $P(18)$ , that depends on  $P(6)$ , traces back to the statement  $P(2)$ . In general, one checks that the truth of  $P(n)$  depends on the base case  $P(\lfloor n/3^{\lceil \log_3 n \rceil} \rfloor)$ .

Another variation involving a modification of both base and induction steps is sometimes called *Double Induction*.

**Base Step:** Prove  $P(n_0)$  and  $P(n_0 + 1)$ .

**Induction Step:** Prove  $\forall n \geq (n_0 + 2): P(n-2) \wedge P(n-1) \rightarrow P(n)$ .

In terms of our domino analogy, we prove: (I) the first two dominos fall, and (II) if any two consecutive dominos fall, then the very next domino falls. From (I) and (II) we deduce that all dominos fall. This version lies somewhere between weak and strong induction.

The next example concerns the Fibonacci sequence  $F_n$  defined by:  $F_0 = 0$ ,  $F_1 = 1$ , and  $F_n = F_{n-1} + F_{n-2}$ , i.e. each term in the sequence is the sum of the preceding two. Using this recurrence formula, the first few terms of the Fibonacci sequence are easily computed:  $F_0 = 0, F_1 = 1, F_2 = 1, F_3 = 2, F_4 = 3, F_5 = 5$ , etc.

### Example 5

Let  $a = \frac{1+\sqrt{5}}{2}$ , and  $b = \frac{1-\sqrt{5}}{2}$ . Prove that for all  $n \geq 0$ ,  $F_n = \frac{1}{\sqrt{5}}[a^n - b^n]$ .

#### Proof:

Let  $P(n)$  denote the boxed equation above.

**I. Base Step** Observe  $P(0)$  and  $P(1)$  are true:  $\frac{1}{\sqrt{5}}[a^0 - b^0] = 0 = F_0$  and  $\frac{1}{\sqrt{5}}[a^1 - b^1] = 1 = F_1$ .

**II. Induction Step** Let  $n \geq 2$  and assume both  $P(n-2)$  and  $P(n-1)$  are true, i.e. for this  $n$  we have

$$F_{n-2} = \frac{1}{\sqrt{5}}[a^{n-2} - b^{n-2}] \text{ and } F_{n-1} = \frac{1}{\sqrt{5}}[a^{n-1} - b^{n-1}]. \text{ We must show } F_n = \frac{1}{\sqrt{5}}[a^n - b^n] \text{ is true.}$$

The induction hypothesis yields

$$F_n = F_{n-1} + F_{n-2} = \frac{1}{\sqrt{5}} [a^{n-2}(a+1) - b^{n-2}(b+1)].$$

One checks that  $a$  and  $b$  are roots of the quadratic equation  $x^2 - x - 1 = 0$ , whence  $a^2 = a + 1$ , and  $b^2 = b + 1$ . Therefore

$$F_n = \frac{1}{\sqrt{5}} [a^{n-2} \cdot a^2 - b^{n-2} \cdot b^2] = \frac{1}{\sqrt{5}} [a^n - b^n],$$

showing that  $P(n)$  is true.

Together (I) and (II) imply that  $F_n = \frac{1}{\sqrt{5}} [a^n - b^n]$  for all  $n \geq 0$ . ■

**Exercise 3** Let  $F_n$  be the Fibonacci sequence and define  $a$  as above. Show that  $F_n \geq a^{n-2}$  for all  $n \geq 2$ , and hence  $F_n = \Omega(a^n)$ . (Prove this by double induction, not as a consequence of the last example.)

### A Short Introduction to Graphs

The propositional function  $P(n)$  is often some assertion concerning various types of mathematical structures, such as graphs, or trees, or other combinatorial objects. A *graph*  $G$  is a pair of sets  $G = (V, E)$ . The elements of  $V \neq \emptyset$  are called *vertices*, and the elements of  $E$  are called *edges*. Each edge joins two distinct vertices, called its *ends*, and no two edges have the same ends. Abstractly, an edge is an unordered pair of vertices, i.e. a 2-element subset of  $V$ . Two vertices that are joined by an edge are said to be *adjacent*, and an edge is said to be *incident* with its two end vertices. Two edges are said to be *adjacent* if they are incident with a common end vertex. Thus in the example below: vertex 1 is adjacent to vertex 4, vertex 2 is incident with edge 26, and edge 45 is adjacent to edge 53.

Let  $x, y \in V$ . An  $x$ - $y$  *path* in  $G$  is a sequence of vertices starting with  $x$  and ending with  $y$ , in which each consecutive pair of vertices are adjacent. We require that all vertices other than  $x$  and  $y$  be distinct, and that each edge in the sequence be traversed at most once. We call  $x$  the initial vertex and  $y$  the terminal vertex. If  $x = y$ , then the path is called a *cycle*. The *length* of a path is the number of edges traversed by the sequence. In the above example we have:

A 1-6 path of length 5: 1, 2, 4, 5, 3, 6  
 A 1-6 path of length 3: 1, 4, 5, 6  
 Another 1-6 path of length 3: 1, 2, 3, 6  
 A cycle of length 6: 1, 2, 6, 3, 5, 4, 1  
 A cycle of length 3: 6, 2, 5, 6

A graph is said to be *connected* if it contains an  $x$ - $y$  path for every  $x, y \in V$ , otherwise it is called *disconnected*. The example above is clearly connected, while the following example is disconnected.

A *subgraph* of a graph  $G$  is a graph  $H$  in which  $V(H) \subseteq V(G)$ , and  $E(H) \subseteq E(G)$ . In the above example  $(\{1, 2, 5\}, \{12, 15, 25\})$  is a connected subgraph, while  $(\{2, 3, 6, 7\}, \{26, 37\})$  is a disconnected subgraph.

A subgraph  $H$  is called a *connected component* of  $G$  if it is (i) connected, and (ii) maximal with respect to property (i), i.e. any other subgraph of  $G$  that contains  $H$  is disconnected. The above example clearly has three connected components:  $(\{1, 2, 5, 6\}, \{12, 15, 25, 26, 56\})$ ,  $(\{3, 7, 8\}, \{37, 38, 78\})$ , and  $(\{4, 9\}, \{49\})$ . Obviously a graph is connected if and only if it has exactly one connected component.

A graph  $G$  is called *acyclic* if it contains no cycles. A *tree* is a graph that is both connected and acyclic. The connected components of an acyclic graph are obviously trees. For this reason an acyclic graph is sometimes called a *forest*. The following graph is a forest with three connected components.

Observe that the number of edges in each tree of this forest is one less than the number of vertices. This is true for all trees, as we now show.

**Example 6** For all  $n \geq 1$ , if  $T$  is a tree on  $n$  vertices, then  $T$  contains  $n - 1$  edges.

**Proof:**

Let  $P(n)$  be the boxed statement above. We begin at  $n_0 = 1$ , and use the strong induction form IId.

## I. Base step

If  $T$  has just one vertex, then it can have no edges, since in the definition of a graph, each edge must have distinct end vertices. Therefore  $P(1)$  holds.

## II. Induction Step

Let  $n > 1$  and assume for all  $k$  in the range  $1 \leq k < n$ , that  $P(k)$  is true, i.e. for any such  $k$ , all trees on  $k$  vertices contain  $k - 1$  edges. We must show that  $P(n)$  is true, i.e. any tree with  $n$  vertices has  $n - 1$  edges. Let  $T$  be a tree having  $n$  vertices, and remove any edge  $e$  from  $T$ . The removal of  $e$  splits  $T$  into two subtrees, each having fewer than  $n$  vertices. (This follows from some elementary facts about graphs which we omit. See the handout on Graph Theory for details.) Suppose the two subtrees have  $k_1$  and  $k_2$  vertices, respectively. Since no vertices were removed, we must have  $k_1 + k_2 = n$ . By our induction hypothesis, these two subtrees have  $k_1 - 1$  and  $k_2 - 1$  edges, respectively. Upon re-inserting the edge  $e$ , we see that the number of edges originally in  $T$  must have been  $(k_1 - 1) + (k_2 - 1) + 1 = k_1 + k_2 - 1 = n - 1$ , as required.

By the second principle of mathematical induction, all trees on  $n$  vertices have  $n - 1$  edges. ■

## Induction Fallacies

The next three examples illustrate some pitfalls to be avoided when constructing induction proofs. The result in Example A below was proved correctly in Example 6. Here we give an invalid proof of the same fact illustrating an argument that some authors have called the *induction trap*.

**Example A** For all  $n \geq 1$ , if  $T$  is a tree on  $n$  vertices then  $T$  has  $n - 1$  edges.

**Proof:** (Invalid)

**Base Step:** If  $n = 1$  then  $T$  has no edges, since each edge must have distinct end vertices.

**Induction Step:** Let  $n \geq 1$  and let  $T$  be a tree on  $n$  vertices. Assume that  $T$  has  $n - 1$  edges. Add a new vertex and join it to  $T$  with a new edge. To be precise, the new edge has the new vertex at one end, and the other end can be any existing vertex in  $T$ . The resulting graph has  $n + 1$  vertices and  $n$  edges, and is clearly a tree since connectedness is maintained and no cycles were created. By the principle of mathematical induction, all trees on  $n$  vertices have  $n - 1$  edges. □

First note that the base step is identical to that in Example 6, and is correct. For the induction step, the argument attempts to follow IIa, but fails to do so. In this example  $P(n)$  is of the form  $A(n) \rightarrow B(n)$  where  $A(n)$  is the statement “ $T$  is a tree on  $n$  vertices”, and  $B(n)$  is “ $T$  has  $n - 1$  edges”. The induction step should therefore be to prove, for all  $n \geq 1$ , that  $P(n) \rightarrow P(n + 1)$ , i.e.

$$(A(n) \rightarrow B(n)) \rightarrow (A(n + 1) \rightarrow B(n + 1)).$$

To prove this, we should assume  $A(n) \rightarrow B(n)$ , then assume  $A(n + 1)$ , then show as a consequence that  $B(n + 1)$  is true. In other words we should:

- Assume all trees on  $n$  vertices have  $n - 1$  edges
- Assume  $T$  has  $n + 1$  vertices
- Show as a consequence that  $T$  has  $n$  edges

The argument did not follow this format however. Instead it does the following.

- Assume  $T$  has  $n$  vertices
- Assume  $T$  has  $n-1$  edges
- Construct a new tree from  $T$  having  $n+1$  vertices and  $n$  edges

Therefore the argument was not a proof by induction. Some students would nevertheless hold that the argument is still valid, even though it is not a true induction proof. The next example shows convincingly that it cannot be valid.

**Example B** For all  $n \geq 1$ , if  $G$  is a connected graph on  $n$  vertices, then  $G$  has  $n-1$  edges. (**False!**)

We notice right away that the above statement is false, since the graph below provides an elementary counter-example. But consider the following “proof” in light of Example A.

**Proof:** (Invalid)

**Base Step:** If  $n=1$  then  $G$  has no edges, since each edge must have distinct end vertices.

**Induction Step:** Let  $n \geq 1$  and let  $G$  be a connected graph on  $n$  vertices. Assume that  $G$  has  $n-1$  edges. Add a new vertex and join it to  $G$  with a new edge. The resulting graph has  $n+1$  vertices and  $n$  edges, and is clearly connected. By the principle of mathematical induction, all connected graphs on  $n$  vertices have  $n-1$  edges.  $\square$

Observe that Example B follows the format of Example A exactly. Thus if A is valid, so must B be valid. But the assertion “proved” in B is false! Therefore B cannot be a valid argument, and so neither is A.

**Example C** All horses are of the same color.

**Proof:** (Invalid)

We prove that for all  $n \geq 1$ : if  $S$  is a set of  $n$  horses, then all horses in  $S$  have the same color. The result follows for any finite set of horses, which includes the set of all horses. Let  $P(n)$  be the boxed statement, and proceed by induction on  $n$ .

**Base Step:** Let  $n=1$ . Obviously if  $S$  is a set consisting of just one horse, then all horses in  $S$  must have the same color. Thus  $P(1)$  is true.

**Induction Step:** Let  $n > 1$  and assume that in any set of  $n$  horses, all horses are of the same color. Let  $S$  be a set of  $n+1$  horses, say  $S = \{h_1, h_2, h_3, \dots, h_{n+1}\}$ . Then the sets

$$S' = \{h_2, h_3, \dots, h_{n+1}\} = S - \{h_1\}$$

and

$$S'' = \{h_1, h_3, \dots, h_{n+1}\} = S - \{h_2\}$$

each contain exactly  $n$  horses, and so by the induction hypothesis all horses in  $S'$  are of one color, and likewise for  $S''$ . Observe that  $h_3 \in S' \cap S''$  and that  $h_3$  can have only one color. Therefore the color of the horses in  $S'$  is identical to that of the horses in  $S''$ . (Note  $n > 1 \Rightarrow n \geq 2 \Rightarrow n+1 \geq 3$ , so there is in fact a third horse, and he can have only one color.) Since  $S = S' \cup S''$  it follows that all horses in  $S$  are of the same color. Thus  $P(n+1)$  is true, showing that  $P(n) \rightarrow P(n+1)$  for all  $n > 1$ . The result now follows by induction.  $\square$

Obviously the proposition being proved is false, so there is something wrong with the proof, but what? The base step is certainly correct, and the induction step, as stated, is also correct. The problem is that the induction step was not quantified properly. We should have proved  $\forall n \geq 1: P(n) \rightarrow P(n+1)$ . Instead we proved (correctly) that  $\forall n > 1: P(n) \rightarrow P(n+1)$ . Indeed it is true that  $P(2) \rightarrow P(3)$ ,  $P(3) \rightarrow P(4)$ , and  $P(4) \rightarrow P(5)$ , etc., but we never proved (and it is false that)  $P(1) \rightarrow P(2)$ . In terms of the domino analogy, it is as if the first domino falls; and if any domino indexed 2 or above were to fall, then the next domino would fall; but the first domino is not sufficient to topple the second domino, and hence no domino other than the first actually falls.

### Justification of the Induction Principles

Here we prove the validity of the first and second principles of mathematical induction (1<sup>st</sup> PMI and 2<sup>nd</sup> PMI). Both principles follow from a basic property of the integers, called the *well ordering property* (WOP), which says: *Any non-empty set of positive integers contains a least element*. We assume this property, for the moment, without proof.

#### Theorem 1 (1<sup>st</sup> PMI form IIb)

For any propositional function  $P(n)$  defined on the positive integers, the following sentence is true:

$$[P(1) \wedge (\forall n > 1: P(n-1) \rightarrow P(n))] \rightarrow \forall n \geq 1: P(n)$$

#### Proof:

Assume that  $P(1)$  and  $\forall n > 1: P(n-1) \rightarrow P(n)$  are both true. Let  $S = \{n \in \mathbb{Z}^+ \mid P(n) \text{ is false}\}$ . It is sufficient to show that  $S = \emptyset$ , since then  $P(n)$  is true for all  $n \geq 1$ . Assume, to get a contradiction, that  $S \neq \emptyset$ . Then, by the well ordering property of  $\mathbb{Z}^+$ ,  $S$  contains a least element, call it  $m$ . Since  $P(1)$  is true, we have  $1 \notin S$ . Therefore  $m > 1$ , and  $m-1$  is a positive integer. Since  $m$  is the smallest element in  $S$ , we must have  $m-1 \notin S$ , whence  $P(m-1)$  is true. We have assumed for all  $n > 1$  that  $P(n-1) \rightarrow P(n)$  is true. In particular for  $n = m$ , we have  $P(m-1) \rightarrow P(m)$ . Since both  $P(m-1)$  and  $P(m-1) \rightarrow P(m)$  are true, we must conclude that  $P(m)$  is also true. Thus  $m \notin S$ , contradicting the very definition of  $m$  as the smallest element in  $S$ . Thus our assumption was false, whence  $S = \emptyset$  as required.  $\blacksquare$

#### Theorem 2 (2<sup>nd</sup> PMI form IId)

For any propositional function  $P(n)$  defined on the positive integers, the following sentence is true:

$$[P(1) \wedge (\forall n > 1: (\forall k < n: P(k)) \rightarrow P(n))] \rightarrow \forall n \geq 1: P(n)$$

#### Proof:

Assume  $P(1)$  and  $\forall n > 1: (\forall k < n: P(k)) \rightarrow P(n)$  are true, and again let  $S = \{n \in \mathbb{Z}^+ \mid P(n) \text{ is false}\}$ . As before we show  $S = \emptyset$ , hence  $P(n)$  is true for all  $n \geq 1$ . Assume that  $S \neq \emptyset$ . By the well ordering property,  $S$  contains a least element  $m$ . Since  $P(1)$  is true, we have  $1 \notin S$ . Therefore  $m > 1$ , and  $m-1 \geq 1$ .

Since  $m$  is the smallest element in  $S$ , we have for any  $k$  in the range  $1 \leq k \leq m-1$  that  $k \notin S$ , whence  $P(k)$  is true. In other words,  $\forall k < m: P(k)$  is true. Now we have also assumed for all  $n > 1$ , that  $(\forall k < n: P(k)) \rightarrow P(n)$  is true. In particular, when  $n = m$ , we have  $(\forall k < m: P(k)) \rightarrow P(m)$ . Since both  $\forall k < m: P(k)$  and  $(\forall k < m: P(k)) \rightarrow P(m)$  are true, we conclude  $P(m)$  is also true. Thus  $m \notin S$ , again contradicting the definition of  $m$  as the smallest element in  $S$ . Our assumption was therefore false, and hence  $S = \emptyset$  as required. ■

Although we proved both theorems independently, it is possible to show that each implies the other, i.e. theorems 1 and 2 are logically equivalent. In fact both theorems are equivalent to the well ordering property itself. We prove below that the well ordering property (WOP) follows from the 2<sup>nd</sup> PMI, and leave the remaining equivalences as an exercise. The terms “strong” and “weak” induction are therefore in some sense misnomers, since neither theorem is really stronger than the other. The term “strong induction” refers instead to the stronger assumption being made in the induction step.

**Theorem 3** (The well ordering property)

Any non-empty set of positive integers contains a least element.

**Proof:**

Assume  $S$  is a set containing only positive integers and  $S \neq \emptyset$ . We must show that  $S$  contains a smallest element. Since  $S \neq \emptyset$ , it must contain at least one positive integer  $n$ . We prove the following fact using strong induction form IId: if  $n \in S$ , then  $S$  contains a least element.

- I. If  $1 \in S$  then certainly 1 is the least element of  $S$ , since 1 is less than or equal to all positive integers.
- II. Let  $n > 1$  and assume for all  $k$  in the range  $1 \leq k < n$  that:  $k \in S \Rightarrow S$  contains a least element. We must show that  $n \in S \Rightarrow S$  contains a least element. Suppose  $n \in S$ . If it is the case that  $n \leq k$  for all  $k \in S$ , then  $n$  is the least element in  $S$ . If not, then there exists a positive integer  $k < n$  with  $k \in S$ . The induction hypothesis now guarantees that  $S$  contains a smallest element. In any case,  $S$  contains a least element.

It follows from the 2<sup>nd</sup> PMI that any non-empty set of positive integers contains a least element. ■

**Exercise** Prove that 1<sup>st</sup> PMI  $\Rightarrow$  2<sup>nd</sup> PMI.

When this exercise is done, we have the implications WOP  $\Rightarrow$  1<sup>st</sup> PMI  $\Rightarrow$  2<sup>nd</sup> PMI  $\Rightarrow$  WOP, which proves the logical equivalence of all three statements.
